alexandria.

investor brief

Benjamin a. Mowinckel — est. March 2026

Alexandria is a tribe of people who put their minds into writing so AI thinks with them, not for them.

Most AI investments cannot defend their terminal value. Alexandria's compounds with every model release — especially post-singularity.

the investment.

Five beliefs install the cheque.

> **1.** *Most AI products are transition assets — value is the gap between model capability and user need; the gap closes with every release; value decays into the model.*
>
> **2.** *Companies that survive are the ones where every model release amplifies the asset rather than absorbing it.*
>
> **3.** *Alexandria's asset is a private, accumulating, machine-readable record of how a specific person thinks — sovereign to the user, unsynthesizable from outside, compounding across years that cannot be back-filled.*
>
> **4.** *The strategic prize is the canonical write path and permission layer for those records — the convention slot, shape of WordPress, GitHub, Hugging Face. Winner-takes-most.*
>
> **5.** *Technical risk is zero. Survival risk is zero. The only existential question is demand. That is the only thing capital is for.*

Capital does not keep this company alive. It runs on ~$100/month and the founder builds regardless. *Capital accelerates the demand experiment, network density, and the first public referee for the category.* The best investor is not the largest cheque — *it is the one whose conviction creates the most leverage.*

the asset.

A structured, machine-readable record of who each user is — whatever they choose to put in it: worldview, values, mental models, taste, personal thoughts, decisions, blind spots, anything. **The product is the framework; the practice is theirs.** Some users run daily Socratic sessions; others keep journals, log decisions, dump streams of consciousness, build their own ritual. **Sovereign to the user. Portable across every AI provider. Worth more from every better model.**

The record cannot be back-filled. Inbox-scraping reaches what the user does, never what they mean. Five years of capture cannot be compressed into a six-month rush. **The compounding is the years.**

Engineering is done. *One curl command, local files on the user's own machine, two integration points fire whenever the user talks to an AI — capture and inject. Ten dollars a month, free with five referred friends.* The only open question is whether enough people want it.

the survival test.

Does this company get better or worse when the next model drops?

Most AI products degrade — coding assistants, productivity wrappers, content generators absorbed into each model release. **That is not terminal value. That is an exit timeline dressed as a multiple.**

Alexandria gets better. *Each user's record is private, accumulating, unsynthesizable from public sources. Better models extract deeper signal from the same record.* Every release is a tailwind.

In April 2026 Andrej Karpathy publicly described this architecture — raw data compiled into structured markdown, incrementally enhanced, queries that compound back into the knowledge base — and said *"there is room here for an incredible new product."* **Alexandria had already shipped it.** The category will exist. The open question is who owns the protocol.

the stake.

The demand for this asset is structural, not aspirational.

AI commoditises capability — strength, intelligence, empathy in sequence. *The cultural premium on human authorship inflates as commoditisation deepens.* **The grandmother's blanket is the grandmother's blanket because she made it.** A factory robot weaving the identical blanket is not the same blanket. The people who develop the *who* behind the work capture the premium. Everyone else competes on artifacts AI can replicate.

The deeper risk is decay. *AI removes the demand on cognition; cognition only develops to the level of demand placed on it; the faculty that would notice the loss is the faculty that has weakened.* WALL-E for the body is science fiction. **WALL-E for the mind is the default trajectory.**

Keep thinking. *That is the rally and the practice. Alexandria is the gym.*

the moat.

*Technical moats die when intelligence commoditises. Even the data isn't a moat — **Alexandria is sovereign by design; any individual user can take their files and walk away at zero cost.** That's deliberate.*

The defensibility is one layer up: coordination. *Alexandria only works as the read **and** write path for personal thought — writers chase readers; readers chase writers; both terminate on the same place.* Once that's where the network gathers, individual exits don't change anything — the value lives in everyone else still being there. **Displacing Alexandria requires getting the entire network to switch simultaneously. That doesn't happen.**

This is how every durable protocol has worked. HTTP, SMTP, GitHub, Hugging Face — open by design, technically replaceable, practically untouchable. **The scarce asset in a world of cheap intelligence is not capability; it is coordination.** Alexandria's bet is to be the coordination point for personal cognition.

Three reinforcing forms of that coordination:

1. Convention. *The canonical place where thoughtful people host their cognitive records — "build it on WordPress," "push it to GitHub," "host your mind on Alexandria."* Once the convention settles, individual exits don't shift it. **Apple can build the tool; Apple cannot build the cathedral.** *Winner-takes-most. The 12–36 month window is now.*

2. Network. *Your circle being on Alexandria means your AI can read their frames when planning with or about them; their AI reads yours.* The friend's-mind primitive makes recruitment a self-interested act — *invite your circle for your own benefit.* A clone can host identical files but starts with no population.

3. Integration. *Every AI tool, agent, and app that reads from the user's local Alexandria directory is another terminal point the coordination terminates on.* Today: Claude Code, Cursor, Codex hooks. Tomorrow: every personalised app and agent. **The user can always leave; the ecosystem points back because the coordination is here.**

Two objections answered:

"Frontier labs will build this." They won't. **Sovereignty is the opposite of their business model** — every dollar spent on neutral user-side infrastructure is a dollar not spent on the next training run. Cross-tool credibility requires a neutrality no single lab can offer. *Every memory feature labs ship validates the demand without competing with it.*

"BCI will read inner speech and kill the asset." It won't. Decoded neural activity is **generically readable but not individually meaningful** — meaning requires the user's own reference frame to interpret. Stanford's Willett (2025) hit 62 words per minute of decoded inner speech; even at perfect readout, the signal is uninterpretable without the frame. **BCIs are the bridge; Alexandria builds what crosses it.**

the business.

Two revenue streams compound on the same users.

Subscription. *$10/month floor — and users choose what they pay above that, no cap.* Prosumer comparables (Cursor, ChatGPT Pro, Notion AI) show that people willingly pay $20–$60/month for tools they actually value. Stands alone. **Break-even at 10 paid users.**

Platform. *Users grant other services permissioned access to their Alexandria record — opt-in, revocable per service.* AI labs pay for alignment and personalisation research data. Consumer apps pay to know users who knowingly want to be known (meditation, therapy, dating, productivity, healthcare). **The user monetises their own frame; Alexandria captures a clearing fee on every transaction.** *Independent of subscription count.*

If	Then
~100K paying users × $50/m settled	~$60M ARR
Platform / integration revenue	~$40M+ ARR
Combined at standard 10× SaaS multiple	**$1B+ valuation**

If subscription saturates short of 100K, platform carries the upside. If platform stays narrow, subscription scales on its own. Single-mode failure risk drops.

the founder.

At pre-seed, the moat is the founder. **The cheque is on the person.**

Benjamin a. Mowinckel. Norwegian-American, 26. Eton, Princeton, Norwegian military, brief stint at Verdane. Currently in San Francisco.

No technical credentials. No previous ventures. The pitch rests on those credentials being irrelevant *— and on the company being the proof.* **Solo, running the entire stack on AI agents at $100/month opex, full-time since March 2026.** Two months from zero to engineering-done.

The hard part is not technical. *A capable team with AI could rebuild the stack in a week.* **Most AI founders solve engineering problems. Benjamin solves the framing problem.**

	$/m
Company opex	$100
Founder bare minimum	$500
Founder safe monthly	$5,000

He cannot be price-pressured. He cannot be runway-rushed. *The floor of this investment is structural — he will be working on this in five years, regardless.*

Princeton cohort, all under 27, frontier of their fields: *the founder of the RL company Anthropic uses for computer-use agents; one of the youngest macro pod leaders at Millennium; a Bain Capital associate; an Oxford PhD with the Larry Ellison Institute; the head of the Norway branch of a US defence company; a US Army Ranger candidate.* **The thinking happens inside this conversation.**

In his own words: *"I could be wrong. I doubt it. The company costs $100 a month. If I am wrong, the world loses nothing. If I am right and nobody builds this, the world loses something it did not know it needed. Either way, I am building it. I can see myself working on this for the rest of my life — through the transition and after."*

what could go wrong.

Demand untested at scale. Acknowledged. *The only open question. The only thing capital is for. Rung 1 directly answers it.*

Convention slot taken first. Real risk. *A better-funded entrant could land "host your mind on X" before us.* Mitigated by move-as-if-12, public artifacts shipping continuously, and founding-cohort velocity. **Not eliminated — that's why the 12-month window is a strategic constraint, not a stylistic one.**

Pain not acutely felt. *Frame imposition required before conversion.* Once the record compounds, leaving feels like loss. **The acquisition problem is not "convince someone this matters." It is "make not-trying feel irrational."**

Capture bottleneck. *Most users have no digital interior.* The daily session is itself the capture mechanism. *Capture infrastructure shipped — desktop + iOS one-tap.*

Solo founder, no track record. *Mitigated by the company being its own demonstration of the thesis, the Princeton cohort, and the Karpathy-validated architecture. Not eliminated.*

Alexandria asks the user for marginal everything — marginal money, marginal time, marginal attention. Downside is zero. **The bet is conviction, not proof.**

the ask.

Three rungs. *Investor chooses where to enter. No fixed round size.*

Rung 1 — ~$100K. *Buffers the founder in SF for ~20 months while the demand experiment runs.* If it works, the existential questions are answered. **If it fails, the loss is less than a bad pre-seed bet on an AI wrapper whose terminal value evaporates with the next model.**

Rung 2 — ~$200–500K. *Scales what works. First 1,000 users. SF presence at scale.*

Rung 3 — ~$1M+. *Platform pilot for AI labs. First public referee on the cap table.*

The company does not need the money. *The founder builds regardless.* Capital accelerates the only experiment that matters.

Returns are the long call option. Legacy is the more certain payoff.

Every protocol that mattered had a first funder. HTTP had CERN. Ethereum had Joe Lubin. The early internet had DARPA. Alexandria is the cognitive layer of AI — the protocol that makes AI think *with* you, not *for* you — and right now it is open. *The firm whose name attaches becomes the firm that goes on the page about how humans preserved thinking through the AI transition. In thirty* *years that page exists. The question is who is on it.*

Athens, Rome, America, Alexandria. **America protects the right to think. Alexandria protects the ability.**

Set the angels free.
